METHOD OF PRODUCING PNEUMATIC TIRES

BACKGROUND OF THE INVENTION

1. Field of the Invention

5 [0001] The present invention relates to a method of producing pneumatic tire having improved lateral rigidity and steering stability performance.

2. Description of Related Art

[0002] It is known that tire generates a cornering force to counteract a centrifugal force acting on a vehicle upon cornering behavior thereof, and a poor cornering force relative to the centrifugal force tends to cause lateral slips of the tire, resulting not only in failure to passing a curved road at high speed, but also in spinning of the vehicle, as the case may be.

[0003] In order to increase the cornering force and thereby improve the steering stability performance of tires, it is desirable to improve the lateral rigidity of tires. Typically, the lateral rigidity of tires is improved (i) by increasing the modulus or volume of the bead filler rubber having a substantially triangular cross-section that extends from the bead core to the end of the tread portion, (ii) by increasing the end count of cords of the reinforcing cord layer or so-called "insert ply", that is arranged along the bead filler rubber in the region ranging from the bead portion to the side wall portion, and/or (iii) by increasing the number of sheets of insert plies. However, these measures are not always effective solutions from practical viewpoints.

[0004] Thus, for example, it is often difficult to extrude bead filler rubbers with increased modulus, thereby causing limitations in terms of production technology. Also, in terms of tire performances, the increased modulus of the bead filler rubbers make it difficult to realize a satisfactory damping performance of the tire, thereby deteriorating the riding comfort

00158 - 1/15

- 2 -

performance, or reducing the cornering force at a slip angle that exceeds the maximum cornering force. The reduced cornering force may result in a sudden change of the limiting behavior characteristics of a vehicle upon cornering, or in spinning of the vehicle. Furthermore, an increased volume
5 of the bead filler rubber brings about not only an increase in weight of the tire, but also elevation of the temperature at the bead portion during driving, thereby deteriorating the durability of the bead portion against heat generation.

[0005] Moreover, even an increased end count of the cords in the insert
10 ply and/or an increased number of insert plies are still insufficient for satisfactorily achieving the desired steering stability performance since, when a lateral bending force acts on a tire that is affected by a slip angle, the insert ply on the compression side does not contribute to improve the rigidity, unlike the insert ply on the pulling side.

15 [0006] In order to improve the lateral rigidity of tires from another viewpoint, there has been proposed a rubber insert layer in which short fibers are embedded. Such proposal is disclosed, e.g., in JP-A-6-192479, JP-A-7-18121, JP-A-8-108713, JP-A-10-315717, etc. It has been confirmed that the rubber insert layers with short fibers embedded therein
20 serves to improve the lateral rigidity of tires satisfactorily, without the above-mentioned drawbacks of the prior art. However, the provision of such rubber insert layers requires an additional time for the molding operation besides that the molding operation itself is complicated, thereby deteriorating the productivity.

25 SUMMARY OF THE INVENTION

[0007] It is therefore an object of the present invention to eliminate these problems and provide a method for producing tires, that can be carried out with simplified operations and under a high productivity, while realizing the

00158 - 2/15

- 3 -

required lateral rigidity and steering stability performance of the tire.

[0008] To this end, according to the present invention, there is provided a method of producing a pneumatic tire comprising a pair of bead portions, a pair of side wall portions extending from the respective bead portions, a tread portion between the side wall portions, a radial carcass ply toroidally extending between the bead portions for reinforcing the side wall portions and the tread portion, reinforcing layers arranged in side surface areas of the tire extending from the bead portions to the side wall portions, respectively; and an inner liner rubber, wherein the method comprises the steps of:

10 - forming said reinforcing layer as an annular laminated body, by spirally winding and laminating a ribbon of an unvulcanized rubber having a thin gauge and embedding short fibers therein; and

 - applying the annular laminated body at a position corresponding to the a side surface area of the tire, between an outer rubber and the inner liner rubber, upon formation of a green tire for the tire to be produced.

15 [0009] The above-mentioned method of the present invention can be carried out carried out with simplified operations and under a high productivity, without the problems of the prior art. Moreover, the tire produced by the method of the present invention includes, on each side surface area, an annular laminated body made of a ribbon embedding short fibers that are arranged with a desired orientation. Thus, when the short fibers in the annular laminated body are oriented in the circumferential direction of the tire, it is readily possible to realize a highly improved lateral rigidity and an excellent steering stability performance without deteriorating the riding comfort.

25 [0010] The annular laminated body may be applied along, and adhered to at least one side of the carcass ply. Additionally, the annular laminated body may be applied along, and adhered to at least one side of a bead filler

- 4 -

rubber. Alternatively, the annular laminated body may be applied to form at least a part of the bead filler rubber.

[0011] The annular laminated body may be preformed by supplying the ribbon from an extruder to a rotating carrier, so that the preformed annular laminated body is applied along, and adhered to the carcass ply and/or a side surface of a bead filler rubber. The performing of the annular laminated body is advantageously preformed during the period in which a green tire is being vulcanized, in order to minimize the loss time.

[0012] Alternatively, annular laminated body may be formed, *in situ*. In this instance, the ribbon may be supplied from an extruder onto a rotating carrier on which the green tire is formed, and laminated and applied along, and adhered to the carcass ply and/or a side surface of a bead filler rubber; thereby forming the annular laminated body.

[0013] Advantageously, the ribbon is applied so that said short fibers are oriented in the circumferential direction of the tire. In this instance, the ribbon is preferably extruded from a positive displacement type extruder.

[0014] Alternatively, however, the ribbon may be applied so that said short fibers are randomly oriented in the reinforcing layer of the tire. In this instance, the ribbon may be extruded from a screw type extruder.

BRIEF DESCRIPTION OF DRAWINGS

[0015] The present invention will be described hereinafter with reference to some preferred embodiments shown in the accompanying drawings, in which:

FIG. 1 is a sectional view showing a tire produced by the method according to the present invention;

FIG. 2 is a sectional view showing a green tire corresponding to the product tire of FIG. 1;

FIG. 3 is a sectional view showing a tire produced by the method

according to a modified embodiment of the present invention;

FIG. 4 is a sectional view showing a green tire corresponding to the product tire of FIG. 3;

FIG. 5 is a sectional view showing an annular laminated body that
5 may be used in accordance with the present invention;

FIGS. 6 to 8 are sectional views of green tires showing various arrangements of the annular laminated body;

FIG. 9 is a perspective view showing one example of positive displacement type extruder that may be used for performing the annular
10 laminated body in the method according to the present invention;

FIG. 10 is a side view showing another example of positive displacement type extruder that may be used for forming the annular laminated body, *in situ*, in the method according to the present invention;
and

15 FIG. 11 is a side view showing a part of FIG. 10 in enlarged scale.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0016] With reference to FIG. 1, there is shown a pneumatic radial tire produced by the method according to the present invention, which is designated as a whole by reference numeral 1. The tire 1 includes a pair of
20 bead portions 2, a pair of side wall portions 3 and a tread portion 4, wherein bead cores 5 are embedded in the bead portions 2, respectively. The tire 1 further includes a radial carcass ply 6 extending toroidally between the bead cores 5, belt layers 7 arranged on the outer side of the carcass ply 6, and an inner liner rubber 8 arranged on the inner side of the carcass ply 6.

25 [0017] In the illustrated embodiment, the bead cores 5 are each comprised of an ordinary core about which a turnup portion 6t is formed by the carcass ply 6 to extend axially from the inner side to the outer side of the tire 1. The carcass ply 6 is comprised of suitable rubber-coated organic

00158 - 5/15

- 6 -

fiber cords, such as nylon cords, polyester cords, rayon cords, etc. The belt layers 7 are comprised of at least two crossed layers of rubber-coated steel cords.

[0018] For the tires 1 to be produced by the method according to the present invention, an alternative arrangement may be adopted wherein the bead cores 5 are each comprised of a pair of strip-like core rings that are arranged side-by-side so that the carcass 6 is clamped therebetween without forming the turnup portion, and/or the carcass ply 6 is comprised of steel cords.

[0019] On each side of the tire 1, a bead filler rubber 9 and a reinforcing layer 10 are arranged in the side surface region of the tire that extends from the bead portion 2 to the side wall rubber portion 3. The bead filler rubber 9 has a generally triangular cross section and extends from the outer periphery of the bead core 5 toward the end of the tread rubber portion 4. The reinforcing layers 10 is comprised of an annular laminated body, the details of which will be detailed hereinafter. It is noted, however, that the reinforcing member 10 in the embodiment of FIG. 1 is applied to the outer side of the bead filler 9 and also applied to at least part of the outer side of the bead core 5. Incidentally, the side surfaces of the tire 1 are each formed by a rubber chafer 11 around the bead portion 2, a side wall rubbers 12 and a portion of a tread rubber 13.

[0020] A green tire 21 is shown in FIG. 2, and has a shape approximating the product tire 1 that is obtained after vulcanization of the green tire 21. Thus, the green tire 21 includes a pair of bead portion areas 22, a pair of side wall portion areas 23 and a tread portion area 24, which correspond to the bead portions 2, the side wall portions 3 and the tread portion 4 of the product tire 1, respectively. The green tire 21 further includes bead cores 25 embedded in the bead portion area 22, a radial carcass ply 26 toroidally

00158 - 6/15

- 7 -

extending between the bead cores 25, belt layers 27 arranged on the outer side of the carcass ply 26, an inner liner rubber 28 arranged on the inner side of the carcass ply 26, bead filler rubbers 29 each extending from the outer side of the bead core 25 toward the end of the tread portion area 24, and a reinforcing layer 30. The side surfaces of the green tire 21 are each formed by a rubber chafer 31 around the bead portion area 24, a side wall rubber 32 and a portion of a tread rubber 33. It is of course that the above-mentioned rubber members in the green tire 21 are still in unvulcanized state.

[0021] A slightly modified pneumatic tire is shown in FIG. 3, which is also produced by the method according to the present invention. The tire 1 shown in FIG. 3 is essentially the same in structure as that of FIG. 1, but differs therefrom in that the reinforcing member 10 is applied to the inner side of the carcass ply 6 and the bead filler 9. The tire 1 shown in FIG. 3 is obtained by vulcanizing a green tire 21 that is shown in FIG. 4.

[0022] With reference to FIG. 5 showing the cross-section as can be seen in a radial plane of the green tire 21, the reinforcing layer 30 in the green tire 21 is in the form of an annular laminated body that is formed by spirally winding and laminating a ribbon 30R of unvulcanized rubber embedding short fibers therein. The annular laminated body 30 is applied to the position of the green tire 21 corresponding to the side surface areas of the tire 1, between the outer rubber formed of the rubber chafers 11 and the side wall portion 12, on one hand, and the inner liner rubber 8, on the other hand. Preferably, the ribbon 30R has a thin gauge within a range of 0.3 mm to 1.2 mm, and a narrow width within a range of 5 mm to 20 mm. The ribbon 30R can be highly efficiently and precisely extruded from a positive displacement type extruder or a screw extruder, which can be operated under an automatic control, and the annular laminated body 30 may be either preformed or formed, *in situ*, upon formation of the green tire 21 in a simple

00158 - 7/15

- 8 -

manner and with a high productivity.

[0023] The short fibers of the ribbon 30R may be randomly arranged in the ribbon 30R, or oriented in the longitudinal direction of the ribbon 30R.

In the latter case, in particular, the annular laminated body 30 forming the reinforcing layer 10 of the tire 1 at its side surface area effectively improves the lateral rigidity of the tire 1 and, hence, the steering stability performance, and also makes it possible to readily and precisely control the steering stability performance including the ride comfort.

[0024] The unvulcanized rubber of the ribbon 30R includes natural rubber (NR), polyisoprene rubber (IR), styrene butadiene copolymer rubber (SBR), butadiene rubber (BR), butyl rubber (IIR), halogenated butyl rubber (X-IIR, X: Cl, Br), chloroprene rubber (CR), ethylene-propylene-diene rubber (EPDM), etc., either alone or in admixture.

[0025] As the short fibers, there may be used polyamide fibers such as nylon fibers, aramid fibers typically known as Kevlar fibers, polyester fibers such as polyethylene terephthalate fibers or polyethylene naphthalate fibers, organic fibers such as rayon fibers. Alternatively, the short fibers may be comprised of wire filaments that are typically used for tire steel cords.

[0026] The unvulcanized rubber of the ribbon 30R may contain known chemical binder such as novolak-type modified phenol resin, in the case of the above-mentioned organic fibers, and cobalt naphthenate or the like, in the case of the above-mentioned wire filaments, and may further contain additives generally used in the industry, such as carbon black, sulfur, vulcanization accelerator, antioxidant, process oil, zinc white, etc.

[0027] The annular laminated body 30 forming the reinforcing layer of the green tire 21 may be arranged along the outer side and/or inner side of the major part of the carcass ply 26, which does not include the turnup portion 26t. Thus, the annular laminated body 30 of the green tire 21

- 9 -

shown in FIG. 2 and FIGS. 6 to 8 is arranged along the outer side of the carcass ply 26, and the annular laminated body 30 of the green tire 21 shown in FIG. 4 is arranged on the inner side of the carcass ply 26. Furthermore, the annular laminated body 30 of the green tire 21 shown in FIG. 2 is
5 arranged on the outer side of the turnup portion 26t, and the annular laminated body 30 of the green tire 21 shown in FIG. 4 and FIGS. 6 to 8 is arranged on the inner side of the turnup portion 26t.

[0028] Also, the annular laminated body 30 may be arranged along the outer side and/or inner side of the bead filler rubber 29. Thus, the annular
10 laminated body 30 of the green tires 21 shown in FIGS. 2 and 8 is arranged along the outer side of the bead filler rubber 29, and the annular laminated body 30 of the green tire 21 shown in FIGS. 4 and 7 is arranged along the inner side of the bead filler rubber 29. Alternatively, the annular laminated body 30 may be applied to form at least part of the bead filler rubber 29, as
15 shown in FIG. 6.

[0029] The annular laminated body 30 may be preformed in advance, and applied to a desired position during formation of a green tire. Alternatively, the annular laminated body 30 may be formed and applied, *in situ*, during formation of a green tire.

[0030] In order to preform the annular laminated body 30, as shown in
20 FIG. 9, a positive displacement type extruder 40 is advantageously used in combination with a carrier device 41 that includes a rotatable carrier 42 in the form of a disk. The ribbon 30R having a thin gauge is continuously extruded from an extrusion nozzle 43 of the extruder 40 and supplied onto
25 the carrier 42 under a continuous rotation about a vertical axis in the direction of by arrow R₁, to thereby form the annular laminated body 30 having a required cross-sectional shape as shown in FIG. 5. By way of example, the preformed annular laminated body 30 shown in FIG. 9 also

00158 - 9/15

- 10 -

forms the bead filler rubber 29 of the green tire 21 shown in FIG. 6. Thus, during the rotation of the carrier 42, the ribbon 30R is continuously supplied and moved radially outwards and thereby successively laminated from the outer peripheral surface of the bead core 25 that is fixedly held in place from the inner side by a radially expansible clamp 44. There may be instance in which the ribbon 30R has to be moved back radially inwards in order to obtain a required gauge. The laminating operation is continued until the predetermined cross-sectional shape of the preformed annular laminated body 30 is achieved.

- 10 [0031] It is preferred that the positive displacement type extruder 40 can be moved back and forth relative to the carrier 42 in two axial directions, including a horizontal direction indicated by arrow Y_1 , that is perpendicular to the rotating axis of the carrier 42, and a vertical direction indicated by arrow Z_1 , that is parallel to the rotating axis of the carrier 42. The extruder 15 40 shown in FIG. 9 is provided with a pair of slide bearings 47 which are guided by, and slidable along a pair of guide rails 46 on a base 45, a movable table 48 to which the slide bearings 47 are secured, and an elevating stand 49 which is mounted on the movable table 48. The movable table 48 and the elevating stand 49 are associated with respective servomotors, not shown, 20 for controlling the movement of the carrier 42 in the two axial directions Y_1 and Z_1 . Incidentally, the blended material of unvulcanized rubber and the short fibers for the ribbon 30R are supplied to the extruder 40 through a hopper 50.

- [0032] The above-mentioned combination of the positive displacement 25 type extruder 40 and the rotatable carrier 42 can be used advantageously, to preform the annular laminated body 30 of the green tire 21 shown in FIGS. 2, 7 and 8, as well. Use of a positive displacement type extruder 40, such as that shown in FIG. 9, is highly suitable when, in particular, it is desired that

00158 - 10/15

- 11 -

the short fibers in the ribbon 30 are oriented in the extruding direction and, hence, in the circumferential direction of the annular laminated body 30.

However, it is also possible to use a small sized extruder of a single screw type (not shown), when it is desired that the short fibers are relatively

5 randomly arranged in the ribbon 30. The preforming of the annular laminated body 30 is preferably carried out during the period in which the green tire is subjected to vulcanization, in order to minimize the loss time.

[0033] On the other hand, in order to form the annular laminated body 30, *in situ*, as shown in FIGS. 10 and 11, an extruder 60 is used in combination
10 with a carrier 61 that is rotatable about a horizontal axis X. The extruder 60 is installed on a floor surface FL is used for continuously extruding the ribbon 30R having a thin gauge, from an extruding die 63 at the tip end portion of an extruding head 62. The ribbon 30R extruded from the extruder 60 is supplied, via a pair of guide rollers 64, 65, directly to the
15 desired portion of a green tire that is being formed on the carrier 61 rotating in the direction of arrow R₂. Thus, the ribbon 30R is laminated to form the annular laminated body 30 having the required cross-sectional shape, on the green tire which is being formed on the carrier 61. Incidentally, the extruder 60 is supplied with a blended material of unvulcanized rubber and
20 short fibers, from a port 66.

[0034] It is preferred that the extruder 60 is a positive displacement type extruder, when the short fibers in the reinforcing layer of the tire are oriented in the circumferential direction. In the embodiment shown in FIG. 8, the extruder 60 thus includes a gear pump 67 at an extruding tip end portion so
25 that the blended material is positively displaced from the gear pump 67 and supplied to the extruding head 62 via an inner flow passage 68.

[0035] The guide rollers 64, 65 arranged in pair constitute a roller die D_R at their opposite surfaces for precisely defining the predetermined cross-

00158 - 11/15

- 12 -

sectional shape of the ribbon 30R having a thin gauge, without causing a so-called die swelling. It is assumed that the distance between the guide rollers 64, 65 can be adjusted, if necessary. The roller 64 also serves as a pressure roller for adhering the ribbon 30R onto the desired portion of the green tire being formed on the carrier 61, under suitable tension and pressure.

[0036] It is assumed that the extruder 60 can be moved back and forth in the directions indicated by double arrow Y_2 in FIG. 10, which is perpendicular to the rotating axis of the carrier 61. Thus, the extruder 60 can be moved toward the carrier 61 during the operation, and away therefrom when it is out of operation. The extruder 60 during the operation can be moved also in the axial directions, parallel to the rotating axis X of the carrier 61. Advantageously, the operation of the extruder 60 is automatically controlled, with the movement of the extruder 60 controlled by appropriate servomotors, not shown.

[0037] As described above, the method according to the present invention can be carried out with simplified operations and under a high productivity, without the problems of the prior art. Moreover, the tire 1 produced by the method according to the present invention includes an annular laminated body made of a ribbon embedding short fibers that are arranged with a desired orientation. When, in particular, the short fibers in the annular laminated body are oriented in the circumferential direction of the tire, it is readily possible to realize a highly improved lateral rigidity and an excellent steering stability performance without deteriorating the riding comfort.

[0038] While the present invention has been described above with reference to certain preferred embodiments, it is of course that various changes and/or modifications may be made without departing from the scope of the invention as defined by the appended claims.

00158 - 12/15
